This is the mechanism which allows you to connect a USB device to a computer and access its content (for example, a mobile phone, an external hard drive, a digital camera, etc.). This class (or class) is a member of the Mass Storage Class Device Subclass (MSC) of the USB Device Class. There is plenty of information available on the Internet about the MSC spec, and the basic idea of USB Mass Storage class is pretty simple, but in this article we will focus only on the USB Mass Storage framework and protocols. Let's start by talking about the logical USB Mass Storage protocol stack: These protocols are used as a framework for the end-users to read and write to USB Mass Storage. The protocols mentioned in the table above will be discussed in the following order. First, we will discuss SCSI—the super-control (SCSI) protocol of the MSD device. Next, we will talk about Bulk transfer protocol. Then we will proceed to the command line request. Lastly, we will move on to the scsi command set. The SCSI Protocol Unlike the earlier protocols that we've discussed, the SCSI protocol is based on the UNIX sockets. SCSI packets are sent and received over the UNIX socket interface. The packets contain a header, payload, and trailer. The header comprises the SCSI command code (specifically, SCSI commands 5-11). Although the SCSI protocol is fairly simple and easy to understand, it has a number of restrictions. Let's talk about the protocol structure.
